

What is the clinical significance of VHL P146fs (c.437del) in Von Hippel-Lindau Disease in CIViC?

Understood! I'll look up the clinical significance of the VHL P146fs (c.437del) variant in Von Hippel-Lindau Disease using the CIViC database. I'll search for recent and relevant information, and report back with the details and citations from authoritative sources.

Worked for 1 minute >

CIViC contains one evidence item (EID5544) for the germ-line frameshift variant **VHL P146fs (c.437del)** in the context of Von Hippel-Lindau disease. This evidence comes from a case study in which the c.437del mutation was found in a Brazilian patient with **Von Hippel-Lindau type 1** disease who had central nervous system hemangioblastomas, retinal hemangioblastomas and a clear-cell renal carcinoma. The frameshift causes a premature stop codon at amino-acid 158, and the study notes that frameshift mutations in VHL, a tumour-suppressor gene, provide strong evidence for pathogenicity (ACMG PVS1)

civcdb.org

On the evidence summary page, CIViC classifies this variant as a **predisposing variant** with **uncertain clinical significance**. The evidence direction "supports" that the variant might contribute to Von Hippel-Lindau disease, but because the only evidence is a single case report the clinical significance remains uncertain . Therefore, in CIViC the VHL P146fs (c.437del) variant is reported as a germ-line frameshift predisposing variant for Von Hippel-Lindau disease with **uncertain clinical significance**.
